# What's New in This Release

This version of Composer contains no new features. New versions of Composer are released in conjunction with the Casper Suite, a complete OS X and iOS management solution available from JAMF Software.

## Installation

### Compatibility

Composer is supported on OS X v10.5 and later.

### Upgrading Composer

To upgrade Composer, simply replace it with the most current version.

It is also recommended that you open Composer's Preference window and verify the new Exclusion List.

### Where did the Temp directory go?

In Composer v7.0 and earlier, a directory called Temp is created in the same location as the Composer application. Composer v7.1 and later no longer creates the Temp directory, but utilizes the following directory in its place:

```
/Library/Application Support/JAMF/Composer/
```

Each package that you create with Composer has its own directory structure for contents and other resources.

### How do I create a PreBuilt package?

The PreBuilt package feature is included in Composer v6.0 and earlier. Later versions of Composer allow you to utilize this feature, but in a slightly different way. You are no longer required to create PreBuilt packages in the Temp directory—you can create them anywhere you want. After creating the package, drag its folder to the Sources list in Composer to create a new package source from the specified files and folders.

# Implemented Feature Requests

No feature requests were implemented for this release.

# Bug Fixes and Enhancements

There are no bug fixes or enhancements for this release.

# Known Issues

There are no known issues in this release.
